At my bank, having direct mail deposit qualifies me for certain privileges, but when I applied for them, I was told I was NOT a "direct mail depositor." I disagreed; my paycheck is sent directly to them, and has been for some time. Then, I discovered the key: my account is joint with my wife, and the computer lists her name FIRST. So when they retrieve data about MY accounts....

Some years ago, when I dabbled in real estate, I had several fat listing books, and kept them in order by area, price, and number of bedrooms. The listings were typed, and often contained errors. Some were easy to spot. If the tax district or the number of bedrooms was wrong, it was easy to make a pencil change on my copy and move the listing to the right place in the books.

I notice that real estate agents are computerized these days. They go to a terminal, key in a price range, number of bedrooms, geographic area, etc., and out comes a string of listings. Who makes the corrections? I doubt that anyone does. It wouldn't surprise me to hear that some real estate people "hide" new listings, when submitting them to "Multiple List" data bases, by putting typos into key data fields, to give their own agents "the first shot" at a new listing. Between accidental and intentional typos, I wonder how much of the existing data actually gets to the requestor.

Please don't write in and tell me about good programming practices. That's not my point. Both we and our targets are coming to rely more and more upon data retrieval for our information. Anybody who can read and type can call up data on most of these systems, but only the more innovative people will be able to squeeze out of the system the "hidden" data. Knowing how to do this could depend upon understanding how people behave when they use a data base, and also how the data base itself really works. It could, in fact, become a new cryptologic skill field.
When you have had a good briefing, what are the things that you most readily recall? In all likelihood it will include items such as the command and presence of the briefer and the quality of the graphics. You will remember the organization that sponsored the briefing and those memories will be of a competent and professional outfit. You will know that the topic briefed is:

- very grave;
- requires immediate action by your organization;
- is in competent hands; or
- needs more resources in the out years.

The fallacy of using briefings to bring people "up to speed" is that briefings are not a good medium for the presentation of a lot of objective, factual data. They are, however, an excellent medium for affecting people's attitudes and emotions. In our society we have so thoroughly suppressed our emotions (e.g., "Grown men don't cry") that we would tend to deny that we are even subject to a play on our emotions, especially in some intellectual palace like the National Security Agency. Unfortunately, this leaves us extremely vulnerable to approaches from a nonintellectual angle and the briefer who discovers this vulnerability, either by accident or as an active intellectual discovery, can use this approach to produce consistently "good briefs." This is a fact long known to Madison Avenue and it is equally true here at the Agency.

When you have had a good briefing, what are the things that you most readily recall? In all likelihood it will include items such as the command and presence of the briefer and the quality of the graphics. You will remember the organization that sponsored the briefing and those memories will be of a competent and professional outfit. You will know that the topic briefed is:

- very grave;
- requires immediate action by your organization;
- is in competent hands; or
- needs more resources in the out years.

But you will not recall specifically why you have those feelings.
All this having been said, then, how can we use this knowledge in building a "good brief"? The most basic step is to decide what emotional message, feeling, or attitude you want to inculcate in the listener. Generally, the attitude or emotion will be one favorable to the topic and organization presenting the brief. For instance, a project officer will generally want to leave listeners impressed with the importance of the project so that future requests for support will be favorably endorsed. In short, although briefings are generally thought of as being informational, most briefings are sales pitches. Once the basic message of the briefing is established, all other work should support that message.

In briefing there is no substitute for the competent briefer, a person who speaks with all the self-assurance of a Nobel Laureate but who at the same time compliments and involves the listeners; one who does not preach to them. For some people these qualities are natural, but for most they can be acquired. The secret is lots of practice and the knowledge that you know more about your topics than your listener.

 Armed with this confidence, the briefer should never use a script. If you know what you are talking about, you don't need a script. If you don't know what you're talking about, you shouldn't be briefing. Bishop Fulton Sheen never used any notes on his very successful TV show during the 1950s. When asked about this once, he cited a remark he had heard as a child. An old woman walking out of church was complaining because the bishop had read his sermon from notes. Her question, which impressed Sheen, was "How the devil can he expect us to remember what he's saying when he can't remember it himself?"

Freedom from the script allows the briefer to give the appearance of being extemporaneous as he or she responds to the quips, comments, and questions of the briefee(s). It also permits the briefer to tailor the brief readily to the background and interest of the listener. Finally, the freedom from the script allows the briefer to establish a pace or rhythm for the briefing that enhances the authority and assurance of the presentation.

With the script eliminated, the only tangible form left to the briefing is the graphics. These are as critical as the presence of the briefer and, in fact, can often make the briefer seem more professional and the briefing come across better. In the choice of graphics it is especially important to keep in mind the emotional appeal of the brief. The Chinese writer who said that one picture was worth a thousand words knew what he was talking about, and the proper choice of graphics can save a lot of talk and questions.

For example, consider the graphics in Figures 1 and 2. "Zendian Army Power" (Figure 1) is just a compilation of numbers. The briefee will read it rather than listen to the briefer—and you'd better hope that the briefee doesn't have some spurious knowledge or he might make some comment like "I thought the Zendians had Type Q tanks instead of Type Ys." This sort of question could well be enough to throw an inexperienced briefer off pace or, worse yet, lead to intellectual questioning of every statement.

Figure 1 has has yet another critical flaw: In column 1 the numbers don't add up to the total shown. If the listener notices this, he/she will spend the rest of the briefing adding up any numbers that appear, looking for other errors.

* There are no units in the Zendian Armed Forces with the designator 2 or II because the Zendians consider this number bad luck.
** There are no tanks per se in the Airborne Corps but there are approximately 200 of the so-called "Y-type tanks" that are in reality a lightweight high-speed tracked anti-tank gun.

May 83 * CRYPTOLOG * Page 2
In summary, the key to effective briefing is to remember that briefings should be used to form attitudes or affect emotions, not only to transfer objective facts. The effective brief should have one central underlying attitudinal or emotional message that it is attempting to deliver and all aspects of the briefing must support this. The briefer should not use a script and the graphics should be simple and chosen with an eye to their emotional impact. Facts used in the briefing are much more effective when placed in some sort of comparative context. Slides to be read should be read by the briefee not the briefer.

The briefer can introduce this type of graphic with some line such as "These are the characteristics of ..." (whatever the subject is). The briefer should watch the faces of his audience and move on to the next graphic as soon as the expressions of the listeners show that they have read the graphic.

In closing, I believe it is necessary to comment on the ethics of briefing. It is evident that, armed with information about the weakness of our psyche, an unprincipled bureaucrat can take considerable advantage of his or her colleagues. At present the only sure counter to this is the individual integrity of the briefing organization which must use its power only for pure motives. Unfortunately, a full discussion of the ethics of briefing is beyond the scope of this article, but perhaps some reader may feel an urge to expand on that topic.

Good luck! Good brief!

"Epilogue"

In closing, I believe it is necessary to comment on the ethics of briefing. STILL MORE ABOUT PASSWORDS (U)

A USER VIEWPOINT

The password controversy continues. On the one hand, and others have stressed the need for greater security to avoid potential compromise. On the other hand, and others have made a strong case for short, easy-to-type and memorable passwords to avoid needless errors and frustration on the part of the user. I am in sympathy with both causes, although I violently object to closing paragraph (CRYPTOLOG, Mar 83, p. 38): he states that an easily remembered password is easy to type regardless of length, and that he doubts that a non-typist (i.e., one who does NOT find a long, memorable password easy to type) will use a terminal for very long. I would argue just the opposite. The probability of error rises progressively with each additional character added to the password, especially since characters are not being echoed on the screen. Also, my personal observation has been that the majority of non-secretarial users--linguists, programmers, and managers among them--are in fact either non-typists or poor-to-fair typists, myself included; yet terminal usage among these groups is increasing rather than decreasing, as more and more people become aware of the advantages which a computer terminal can provide to the professional user.

Having said this, let me state that I think the problem is easily solvable in a manner which should satisfy both viewpoints. Instead of viewing the problem theoretically--short passwords are good, but breakable; large alphabets, pass phrases, and "passcodes" are good, but will result in higher error rates--we should take the Agency environment into account. Many Agency computer systems have a feature which automatically "kicks out" anyone who unsuccessfully tries a user ID-password combination three or four times in a row. Those which do not can be easily modified to allow this capability. If the office security manager is alerted to terminals on which three unsuccessful ID-password combinations have been tried, I doubt very much that a hostile entity would have any success in breaking even a five- or six-letter, single-case, mnemonic password before being apprehended. At the same time, a poor typist gets several chances at entering the combination correctly before setting off the alarm. This system thus provides the best of both worlds: a user-friendly password environment which is, for all intents and purposes, immune to exploitation.

P.S. A challenge to all UNIX users: how many of you can type "Low flying bees eat wax beans" (to use example of a pass phrase) and get it right the first time? It's easy to find out: set terminal type to STTY -ECHO; type in the phrase enclosed in single quotes, i.e., 'Low flying bees eat wax beans' and hit <RETURN>. A system message will appear as follows:

```
Low flying bees eat wax beans: not found
```

(or whatever you REALLY typed)

After you're done experimenting, STTY ECHO will make your characters visible again. (At an informal testing in the KEPLER laboratory, I got the phrase right 3 out of 7 times; however, I fall under the "non-typist" category.)

THREE GOOFS AND YOU'RE OUT

On [the system I use], a user signs on with user initials and then is required to type in a password. If the person "fails," they may try again and again and again.... To prevent exhaustive searches, why not flag to the system's operator any console that tries say three times? Or lock that terminal out?
PASSWORDS: FRIEND OR FOE?

Speaking of passwords, what is an acceptable balance between security and convenience? I have found what I believe to be a rather comfortable and simple solution (but then I'm sure SOMEONE will disagree). I simply choose a word...such as walnut, then alter or misspell it (wallnut, waalnut...etc.). Not enough to make it difficult to remember, but definitely making it more secure and harder to guess.

MORE ON PASSWORDS AND HUMAN FACTORS
(from COMPSECNEWS, June 1983)

One of the frequently heard complaints from persons who changed to more clever passwords containing special symbols or mixtures of upper and lower case, was that when bringing some of the terminals up cold, and prior to loading the terminal emulator, they could not login. True that each keycap may not send the same character before an emulator load as it will after, but when those infrequent occasions arise, you can still probably login if you only knew what keys to press. For example, one system I know of uses the "back tab" key to produce the \"\" prior to emulator load. Obviously an inconvenience, but most users do not regularly have to perform initial terminal loads.

Other systems that I have seen have accounts called "LOAD." These accounts do not require the person who logs in to enter a password, only to choose a desired emulator. After the selected emulator is loaded, the real user login is then required. If your system does not have this feature, complain to the system Guru. Incidentally, notice that an emulator load is all that the "LOAD" account can do.

Another comment had to do with the login-id being secret. The suggestion centered around doing away with initials as the login-id, and using a secret account name in addition to a secret password. Maybe a useful idea, but one point missed by this comment was that the current login algorithm used on most of the systems does not reveal what is wrong when the login fails. For example, notice of login failure only appears after the id and the password has already been given. Another problem with this suggestion is we already have a requirement to identify individual use of sensitive computers. Work is currently underway to assign each and every user of our computer systems a unique id that will be the same regardless of which computer system is used. The adopted format will follow first two initials followed by the first five letters of the last name. A central registry is being established to resolve conflicts.

Keep your comments coming! In particular, I would like to see more comments from users about the consequences for them of various access restrictions, password procedures, etc. How have some practices on the systems YOU use hindered or helped YOU in your work? I know that it is fun for a lot of you ingenious people out there to think up new password schemes and gimmicks, but the computer security experts are pretty inventive and ingenious too. What they need, more than new techniques and ideas, is some clear feedback from users about the costs and benefits of different kinds of procedures currently in use. If they get a clear indication from users that certain methods of implementing access restrictions impose a relatively high cost on users, they will be motivated to use their ingenuity to find other and better methods that are just as secure but less costly to the user. I was interested to note, in the COMPSECNEWS item above, the assumptions that
1) users rarely had to load terminals "cold"; and
2) coping with keys that send different characters before and after emulator loading constituted a minor inconvenience at most. What do you think about those assumptions?

As a hunt-and-peck typist, I find odd-ball special characters are a MAJOR stumbling block, even when the keycaps agree with the character that gets sent. Even the shift key and "CTRL" key are frequent error-makers for me. Also, my impression is that users have to down-line-load Delta Data terminals more frequently, at least for some systems, than the COMPSECNEWS editor assumes. In fact, if I had to cope with that problem, even having to load a terminal once a week would be far too often for me! The "LOAD" account mentioned in the article seems to me a much more promising and user-friendly approach than "if you only knew which key to press."

For a programmer, or someone thoroughly familiar with the terminal and software, perhaps keys that send different odd-ball sets of characters at different times may present only a minor annoyance; in fact, computer folk seem to thrive on and positively welcome such problems. Most others, however, are very unlikely to agree with them. Computer specialists, and computer security specialists in particular, need to be reminded that situations constituting brief nuisances or even amusing challenges for them can be stressful and exasperating for other kinds of users.

-M.E.D.

May 83 * CRYPTOLOG * Page 6
DES-type algorithm, using 800-bit vectors in place of the 48-bit vectors of DES, was proposed at GLOBECOM 82 (the 1982 Global Communications Conference) for the encipherment of medical records. The key would be 160,900-bits long. The Belgian author of the paper, Desmedt, claimed that this would protect medical records during the life of the person concerned. In reply to a question, he admitted that he did not know how to keep the 160,900-bit key itself secure and intact for the 100-year period.

(U) The Desmedt paper on super-DES was one of five papers on cryptography presented at GLOBECOM 82 in December. In addition, there were five other sessions on coding, primarily speech coding, which proposed reducing bit rates for video and voice and facsimile. Compression techniques and the ability to recover from channel errors are critical to the use of digital encryption techniques.

(U) Two other surprises were the sophisticated insight into the strengths and weaknesses of various public key schemes, especially the flaws of the Hellmann-Merkle algorithm, and the importance of the recent Racal-Milgo patent on finding large primes for the RSA public key algorithm. Several speakers stated that the RACAL-MILGO algorithm had made the integration of DES and the RSA algorithm feasible as the basis of a switched ad hoc public cryptographic network.

(U) This demonstrated interest in the feasibility of the RSA algorithm as a means of keying DES links is more interesting in the light of the Inman interview (Science, Dec 82), which identified RSA as a secure method.

(U) The leadoff paper by J. Michael Nye, a self-styled cryptographic "expert," described the methods and cost of intercepting telecommunications in the US and gave a list of 26 domestic cryptographic suppliers offering 104 products and 13 foreign vendors offering 81 products in the US market. The list of suppliers and products is growing, and the impact of Personal Computer encryption is yet to be felt. This is a very big change from ten years ago, when only a few companies supplied cipher equipment to the US market. Most of the products are for fixed telephone service, but as the new technology of cellular radio develops over the next decade, the market for voice encryption, to protect the 900-MHz mobile circuits from interception will increase to millions of vehicle radios.

Digital Telephony (U)
(U) Cox, Jayant, and McDermott of Bell Labs gave a paper on a time-frequency segment permutation analog encryption which they believe is very secure against cryptanalytic attack, without loss of voice quality or syllable intelligibility. The delay for the scrambling and descrambling is no more than 256 to 512 milliseconds for 16-msec speech segments. Each 16-msec segment, sampled at 8000 Hz to give 128 samples, is converted to sub-bands by digital filtering, and the sub-band vectors are then permuted. The digital vectors are stored in a buffer with a memory capacity up to 512 msec. A cryptographic keystream decides on the segment permutation, and also decides which time segment will be sent. Any time segment can be delayed up to 256 msec. The input test data were voiced digits in random order, used to avoid the redundancies of normal conversational speech.

(U) The main thrust of the designers' work was to get good intelligibility. They now want to reduce the software algorithm to a hardware device, and VLSI design can follow from there. The audience showed substantial interest in this scheme.

(U) Despite the rapid introduction of digital channels, for many years to come, most of the world's telephone connections will be made over copper circuits that will not support high bit rate digital speech. One of the driving forces behind the development of digital transmission and local loops is the desire for high-quality secure speech. If the hybrid analog-digital scrambling gives good enough speech quality, and no particular security weaknesses become known, the market pressure to develop digital services to the 64,000-bps level IDN (= Integrated Digital Network) may reduce (since customers won't have to buy them) and this could affect an important part of the digitization of the telephone network.

(U) Despite the rapid introduction of digital channels, for many years to come, most of the world's telephone connections will be made over copper circuits that will not support high bit rate digital speech. One of the driving forces behind the development of digital transmission and local loops is the desire for high-quality secure speech. If the hybrid analog-digital scrambling gives good enough speech quality, and no particular security weaknesses become known, the market pressure to develop digital services to the 64,000-bps level IDN (= Integrated Digital Network) may reduce (since customers won't have to buy them) and this could affect an important part of the digitization of the telephone network.

(U) The cryptographic scheme is to fill the buffer with 16-msec segments, then send all of them in some pseudorandom order until the buffer is transferred to the receiving end. Then the buffer is refilled and the scrambling and transmission begin on the next multisegment block of speech. It is not clear from the published paper whether the segment transposition key is the same or changes from block to block.

(U) The scrambler was implemented on the BTL Digital Signal Processor, and tests showed that it gave better intelligibility than simple frequency inversion scrambling. The scrambled signal envelope sounds like "birds chirping." To maintain synchronization, a series of pulses is sent down the channel whenever the scrambling buffer is reinitialized, and these high pitched pulses send like "cricket chirps" interleaved with the signal.

(U) Although the system is described as an "analog" scrambler, it is clearly a 5-stage analog-digital process, in which most of the processing at each end is digital, but the transmitted signal is an analog waveform. It has been tested over the Murray Hill phone system, with addition of simulated white noise and phase roll (a channel impairment).

(U) Because sample-to-sample fidelity is important to speech reconstruction, i.e., the sampled speech at the receiver must match the samples that are supplied to the digital-to-analog (D/A) converter at the transmitter, it is necessary to equalize the channel to compensate for channel distortions and to synchronize the instants of sampling at each end. The synchronization pulses (cricket chirps) are used to establish and maintain sample timing and are also used for channel equalization (since they give the impulse response of the channel).
This is undoubtedly a reflection of the rapid transborder flow of technical information between academicians and the arrival of increasingly capable people into the arena of public cryptology. Without doubt, the technical quality of the work will increase and will threaten SIGINT.

(U) The particular cryptographic scheme that Desmedt et al propose is a version of DES in which blocks of data of 1,600 bits are enciphered, under the control of a 160,900-bit key. The S-boxes of DES are replaced by one-way knapsack functions. This revised "S box," instead of operating on eight bits, operates on 200 bits, and there are eight of them operating in parallel. Each of the new "S boxes" is initialized with 100 integers of 20 bits, so that it contains 20,000 bits. There are eight "S Boxes," which use up 160,000 bits of the key. Because of the trapdoor function, even if the 160,000 bits were known and all the S-box outputs were known, it would still be very difficult to compute the 800-bit input. However, the 160,000-bit key is not known. It is kept secret. That makes it even harder to compute the input from the output. The 200-bit outputs are expanded up to 208 bits and then hashed down to 100 bits to give the 800-bit output. This complicated process is iterated a number of times. A stream or block mode with this algorithm is possible.

(U) The Desmedt paper on Super-DES began with a critique of existing cryptographic methods, interleaved with some familiar commentary on NSA intervention in the DES design. A point of interest is the statement that the Geneva Management Group in 1981 concluded that DES was not adequately secure. Desmedt argues that encryption algorithms that iterate the basic operations many times provide higher security than the individual operations (e.g., substitution, transposition) but are impractical to implement on VLSI chips. He also argues that a DES-breaking special machine may be costly today, but in 20 years could be cheap enough to break messages enciphered on DES now. He also acknowledges that no "shortcut" solution to DES is known. Hellmann's insinuation that a "trapdoor" was built into DES by NSA is referred to. The problem of public key algorithms such as the Merkle-Hellman scheme is described as either they have known weaknesses or they may have unknown weaknesses. What is notable about all of this critique is that the authors are professors of mathematics in Belgium and they are very up-to-date in the state of cryptology in the public domain. (One of them spent 1978-79 at UCLA, Berkeley, doing pertinent research.)
(U) Yiu and Peterson of Hewlett-Packard gave a paper on a single-chip VLSI Public Key algorithm. The algorithm is Hellmann's discrete exponential scheme using Galois Field arithmetic. The chip has 12,000 transistors and is designed for a 4-MHz clock rate. The Public Key algorithm would be used in conjunction with DES, to distribute keys for the DES algorithm. The purpose of the chip design was to give higher speed and lower cost for encryption. The use of Galois Field arithmetic eliminates the need for carry or borrow operations, and the arithmetic operations can be executed by linear feedback shift registers. The developers expect to use the chip in a computer network, but the company, according to Yiu, has no commitment to market it.

(U) Doctor Yiu mentioned the recent Racal Milgo patent for finding large prime numbers in a few seconds as an important breakthrough in implementing Public Key networks. The patent, No. 4,351,982, claims that it reduces microprocessor computation time to find a set of 200-bit primes from 1,200 hours to two hours. Desmedt stated in his talk that the RACAL MILGO datacryptor took only 17 seconds to distribute key (but it was not clear that it would find RSA primes in that short time). Hollander of BTL (Bell Telephone Labs) has a patent application that purports to find large primes very quickly. The Japanese are developing a chip that will do RSA encryption at 50,000 bps. The work is a joint project of NTT, NEC, Hitachi, Fujitsu, and Okl. Sandia has developed an algorithm that will do multiplication modulo C in \( \log_2(C) + 7 \) clock pulses, which is an improvement over the conventional modular multiplication, which takes \( N \times N \) clock pulses for an \( N \)-bit modulus. The Sandia method would take only \( N + 7 \) clock pulses. It is aimed at RSA encryption using 512-bit prime numbers. At 20-MHz clock speed they expect to be able to encrypt at 25 Kbps. Now that the RSA Public Key algorithm has been publicly identified by a former NSA Director as secure, there will undoubtedly be intensified work to make it easier to use to set up DES links. The high utility of being able to dial up any other party and set up a secure link, without prior key distribution, is irresistible from both intellectual and marketing viewpoints.

(U) A paper on the AMD DES chip was given by Brown, an AMD executive. This was followed by some discussion of the merits of DES. Both Yiu and Brown felt that DES was in fact secure, and that the criticism that Desmedt and other authors had raised were not supported by any facts. No one had been able to read or exploit DES, and it had the advantage of a standardized tested algorithm. The AMD DES chip was capable of 1.7 Mbytes/sec, so that it could be used for disc controllers. It cost $75 for a single unit.

(U) Another paper at the cryptographic meeting was an Italian scheme by CSELT for a "robust" 4800-bps speech coder. Audio tapes showed it to be resonant and of low quality. The paper did not seem to offer any important new work. However, the topic of speech coding and other compression coding was treated at five other sessions. There were 31 papers on voice and image compression, of which 16 were by foreign authors. The sessions were:

[] A8 : Low bit rate speech coding
[] B6 : Image processing
[] D4 : European videoconferencing
[] E6 : Advances in speech coding
[] F7 : Speech processing

(U) The interest in compressed speech in sessions A8, E6, and F7 was initially to allow narrowband encrypted voice signals. Now a number of other applications, including low-cost bandwidth conservation and interim storage of voice, have emerged from the capability to compress speech.

(U) The interest in compressed video is for both teleconferences and private TV broadcasts (e.g., Pay-TV, TV relay by satellite, and Direct Broadcast Satellites (DBS)). The common carriers and the broadcasters both see commercial advantages in being able to send TV signals that can be securely encrypted. Because bits/sec cost money, the customers want the pictures compressed.

(U) In Europe there is a multinational effort to develop a standardized videoconference system, with a standard video coder. Some of this is for satellite applications, to thwart interception, but most of it will
probably pass overland on radio relay and optical fibers. The compression allows cheaper conferences and security, and the standardization will allow the Europeans to intercommunicate and keep US companies out of the equipment market.

(U) There are now hundreds of papers published on vocoders, fax coders, encryption, video coding, etc. Many of the papers are foreign, but the Europeans in particular have been handicapped in the speech area, for example, by the lack of specialized journals which consolidate the work. As a result, they look to the US journals, especially the IEEE publications, as the focus of the current work. This also makes it difficult for US parties to keep up with the foreign work because it is spread across a number of journals and is often published in German, French, Italian, Swedish, Japanese, etc. However, the foreign literature is growing, and will become a more important source of new work in cryptography and coding.

(U) The Europeans, arriving on the scene after the US has identified the problems and paid for the basic research, will be able to converge on coding and encryption standards to serve many of their PTT plans, without the competition, confusion, public controversy, and divided purposes that have arisen in the US in both Government and civil coding and encryption. By the end of the decade, they may have passed the US in these fields, just as they have surpassed the US in a number of other selected technologies and industries.

In the chapter on digital switching, the advantage of time-domain switching is shown to be the ease of getting switches that don't suffer from blocking. There is quite a lot of information in the switching chapter. Among other things, the book has a 16-page glossary of pertinent terms, such as burst isochronous, Centrex service, despotic network, elastic store, HDB3 code, justification ratio, mesochronous, muldem, permanent virtual circuit, plesiochronous, robbed digit signaling, state store, transhybrid loss, traveling class mark, and waiting time jitter. These terms are indispensable refinements in educated discussions of networks. This glossary will soon be in the NSA terminology base.

The book covers digital networks from a general overview of the analog network in the US, through voice digitization algorithms (PCM, DPCM, APC, vocoders, etc), fundamentals of digital transmission, switching and multiplexing, through digital modulation, network synchronization and control, to high-level descriptions of several digital networks and a discussion of the future of digital telephony. Among other things, the book has a 16-page glossary of pertinent terms, such as burst isochronous, Centrex service, despotic network, elastic store, HDB3 code, justification ratio, mesochronous, muldem, permanent virtual circuit, plesiochronous, robbed digit signaling, state store, transhybrid loss, traveling class mark, and waiting time jitter. These terms are indispensable refinements in educated discussions of networks. This glossary will soon be in the NSA terminology base.

One of the principal difficulties in making the large telephone network operate is the variety of signals and signaling functions, all of which have to be translated by interfaces or made compatible.

Common Channel signaling in the Bell System is highly centralized, making the entire network vulnerable to failures in the CCIS packet traffic.

If a CCIS node fails to store and forward certain network information correctly, the network will gradually lock up because disconnects do not occur automatically.

Digital microwave radio is cheaper than T-carrier for distances as short as eight miles, and the major impetus for digital radio has been the introduction of digital switches, not the demand for digital traffic, which can pass over the analog network.

Voice digitization, nominally 64,000 bps, can be as great as 400,000 bps for specialized services such as broadcast transmission.

About ten different speech coding schemes are described.

In the chapter on digital switching, the advantage of time-domain switching is shown to be the ease of getting switches that don't suffer from blocking. There is quite a lot of information in the switching chapter. The chapter on network synchronization examines many of the timing problems and the solutions such as bit slips, elastic stores, pulse stuffing, and packetization. The chapter on digital networks leads from ARPANET to the ISDN (integrated services digital networks). Circuit-switched nets are shown to be more efficient for voice transmission than packet-switched nets, but digital speech interpolation can increase the effective number of channels on a trunk if the circuit switching is fast enough. Current circuit switching can operate fast enough so that even the beginnings of syllables are not lost. The final chapter is on traffic analysis, as the traffic engineers and designers do it.

The book is well written and well illustrated, with references and exercises. Because of the integration of transmission and encryption, as well as the continuous growth and switchover into digital networks in every country, a knowledge of the engineering and technology of digital networks will be an essential part of a cryptologic repertoire. Bellamy's book is a good beginning to this knowledge. The enciphered speech cryptanalytic experts in R52 ordered desk copies after reviewing the book.

Summing up, Digital Telephony is timely, gives good coverage of digital networks, and should be a useful text and reference for some years. It costs about $50.
The following cumulative index of CRYPTOLOG (Vols. I through IX, 1974-1982) was produced using UNIX/PINSETTER tools on MYCROFT and BARDOLPH1. The index is in three parts, and is being published in three successive issues. Part one is an index by author; part two is an index by title; and part three is an index by keyword. Items in multiple issues (February-March 1975, for example) are indicated by the first month (i.e., by Feb 75).

**Part Three: Keywords**

P.L. 86-36
The Intelligence Watch Officer (U)

by T52

Want an interesting job? Do you want to be busy--sometimes too busy to eat even when you've brown-bagged? If you are interested in current events and want to know what is going on in the world or what is going to happen next, you may be interested in the Intelligence Watch Officer (IWO) position in the National SIGINT Operations Center.

(U) The author served as Intelligence Watch Officer on Team 3 (P33) in NSOC from September 1981 to January 1983.
I would like to raise a "full glass" in a toast to his article concerning

(U) If you are interested in more information on the Intelligence Watch Officer position in NSOC, contact T5, x3265.

EO 1.4.(c)
P.L. 86-36

(U) During non-regular duty hours, the IWO acts for T5 in receiving and responding to requests for information from NSOC, field sites and 24-hour NSA work areas. The IWO attempts to answer all requests instead of referring them to a day shop for action. This frequently necessitates trips to the NSA Geography and Map Library, the Main Library, or to Central Research to research and retrieve a map or citation to answer the query. The IWO has a one-way pager to carry when away from NSOC for any length of time—he maintains constant contact with NSOC when necessary to receive new requests or operational requirements.

Traffic Analysis [U]

by

The traffic analyst finds himself turning to data systems because he often has mountains of data to examine, because the people who receive TA results usually want their information very rapidly, and because almost all the data the traffic analyst wants to see is already inside a computer somewhere.

(U) Most traffic analysts who try to look at data systems develop a kind of schizophrenia. On the one hand, the TA data that comes in today has to be processed and analyzed today because there will be another batch of data coming in tomorrow. This means that the traffic analyst has to use today's data system to handle today's data. On the other hand, it does seem to us traffic analysts that data systems people would much rather talk about tomorrow's system—the one that isn't here yet, the one that won't have all these glitches and problems that today's system has.

(U) The traffic analyst who is in the trenches on a current operational problem would easily trade all the glowing promises of some brighter tomorrow for a quick fix on some of the glitches in today's system that will keep him from bleeding to death right now. That isn't my subject today—I really want to talk about the future. But as I thought about standing up here in front of all you data systems people, I couldn't resist putting in a plug for the working traffic analyst; he needs your help, both today and tomorrow.

(U) Since our data consisted of a matrix with 80 columns and many rows (one row for each card), our output consisted of that same matrix with its columns and rows transposed in some way. Later, we added the ability to look up words or strings in a dictionary and insert the result back into the matrix.

This paper was presented at the November 1982 Meeting of CISI.
(U) Many years and computer systems later, in the mid-1960s, this was still the primary data systems support to traffic analysts: a transposed matrix (now often wider than 80 columns) with a dictionary lookup. There were attempts to go beyond this. Most of the things we tried were made to fit one specific problem, and never developed into general TA tools. We developed ponderous, monolithic record formats whose structure provided a special place for each variety of data we thought we would find in the traffic. What I remember most vividly are long, soporific meetings where all we ever seemed to talk about was what format the data was going to be in. We spent untold amounts of energy and resources getting all of our data into these unyielding, user-murky systems, and there was often little energy and resources left over to develop any user-friendly output.

(U) The result of this, in many areas, was that the output received by the traffic analyst was not much more than his original raw traffic, transposed both horizontally and vertically, and with some information added through dictionary lookup processes.

(U) It is still possible, even today, to see analysts sitting down with computer output and handlogging data from that computer output onto a form for their own personal use. In at least two areas, one might then see that same handwritten log being used a little later to punch cards for further computer processing!

WHAT IS THE TRAFFIC ANALYST TRYING TO DO?

(U) The traffic analyst is trying to draw a picture of his communications target. He usually wants this picture to show how his target looks when it is operating normally. Once he knows what his target's normal behavior is, then he is in a position to detect variations, and report them to intelligence consumers.

CONTINUITY

(U) Traffic analysts are usually looking for something they call continuity. When faced with a target that has daily-changing callsigns, the traffic analyst seeks to learn which of today's callsigns matches what callsign used yesterday.

If I can say that the station that used callsign ABC on the first day is the same station that used callsign DEF on the second, then I can say that DEF (on day 2) is continuity of ABC (on the 1st). On the third day, if I can say that GHI was used by that same station, then I can add GHI (on day 3) as another link in a growing chain of continuity. Many of our TA targets do change their callsigns, frequencies, addresses, and other features on a regular basis. They do it to
make collection and identification more difficult, and it is the job of the traffic analyst to defeat these changes by the development of continuity.

**TWO KINDS OF TRAFFIC ANALYSIS**

(U) There are two forms of traffic analysis on most problems: development and maintenance. To borrow an example from cryptanalysis, the attack against a cipher system often goes through two phases:

[] first, diagnosing and recovering of the general cipher system, and

[] second, exploiting and processing the recovered system, which often involves solving daily keys or settings.

So too, in traffic analysis, one can consider that there is a development (or recovery) phase and a maintenance (or exploitation) phase, which may or may not include product reporting. However, in traffic analysis, the two phases often occur at the same time.

(U) In some ways, the traffic analysis process resembles a spreading oil blot. Out on the edges, new target territory is being conquered, new target communications structures are being discovered and cataloged; new methods of identifying and distinguishing various communications are being developed. But back in the central part of the oil blot, the territories previously conquered must be kept track of; the continuity of target communications structures previously recovered must be maintained.

**OIL BLOT**

(U) Sometimes the personality of the manager plays a part in just where this point of "no growth" takes place. Some managers are more at home in the settled, stable atmosphere of the center, where things don't change much from day to day. These managers tend to concentrate their attention on building a smooth-running system at the center, and may put a larger proportion of their resources into that area, so that the "no growth" point is reached more quickly. Other managers thrive in the rough and tumble frontier atmosphere out on the edges of the problem, where each day is likely to bring some new and different challenge. These managers tend to concentrate their attention on the recovery effort, sometimes at the expense of the more humdrum maintenance.
TRAFFIC ANALYSIS GOALS

(U) From the standpoint of the two kinds of traffic analysis--development and maintenance--we can express the general goals in the following ways:

TA DEVELOPMENT GOALS

(U) We rarely collect or analyze all of the communications of any given target. We are almost always working on a sample of the target. At any given time, there is some residue of the target that we do not maintain continuity on, and bits and pieces of that residue find their way into our unidentified or search pile--the file of incoming traffic which looks as if it belongs to our target but doesn't exactly fit any of our known continuities. Development TA concentrates on that pile, trying to dig out new target nets and continuities. This unidentified pile is almost like "background noise"; it is always there, whether we talk about it or not. If we are still growing (if the oil blot is still expanding), then our development goal is to dig more of the target out of the unidentified pile. If we have reached the "no growth" point, then our development goal is to be able to recognize and develop any new communications that the target might put on the air--communications that ought to stand out against the "normal noise" in the unidentified pile.

TA MAINTENANCE GOALS

(U) During the maintenance phase, we want to be able to hang on to the continuity that we have already recovered. We want to do this:

[] to support whatever analysis efforts are currently engaged on the target (such as cryptanalysis, language, reporting, etc.), and

[] to support whatever collection effort is working against the target.

(U) To do the first support requirement properly, we need to be able to correctly distinguish and identify each of our continuities as the traffic arrives at the point of analysis, i.e., after it has been collected.

As an aside, I should say here that the reporting side of traffic analysis is generally well ahead of the technical side in the use of computers. Since my primary interest in this paper is the working-level traffic analyst, I will be concentrating on the technical side, and I do not propose to discuss the reporting aspects of TA except as they touch on the technical side.
HOW CAN COMPUTER POWER BE APPLIED TO THE TA PROBLEM?

(5-600) In order to consider how the power of the modern computer might be applied to traffic analysis, we need to look at the model of TA that emerges from these two phases: development TA and maintenance TA. Although I have described them as if they were distinct and separate, they really ought to be thought of as a conjugate pair, because they tend to occur together on most problems. It is also possible for certain problems to be best described as a hybrid of these two forms: during the war in Vietnam, one out of every three pieces of intercepted traffic was unidentified, largely because of the rapidly-changing nature of the target. The point I want to leave with you today is that any attempt to provide the traffic analyst, either here in this building or anywhere in the world, with a Traffic Analysis Workbench System must reckon with the fact that the problem he is working will always be some mixture of these two forms of traffic analysis. We also need to consider that a TA problem can quickly change from one form to the other.

(EO 1.4 (c)) We decided to see if we couldn’t find a way for computers to help us with the more stable maintenance problem. I remember spending several weeks laying out the logic and processes on the problem. And I remember being told, at the end of the project, that there wasn’t nearly enough memory available to do what I needed.

A COMPARISON OF TWO FORMS OF TA

May 83 * CRYPTOLOG * Page 40
A COMPARISON OF TWO FORMS OF TA

(U) Let's look at these two forms of TA a little more closely. How do they compare when we look at them from the viewpoint of providing today's (and tomorrow's) traffic analyst with a computer support toolkit, while using a terminal workstation in an NSA worldwide networking environment?

(U) In development TA (the garrison communications in our example), we have a bookkeeping problem,

[] where the emphasis is clearly on keeping track of a lot of known continuities;

[] where we expect the changes in the target characteristics to be relatively modest;

[] where the technical means of keeping up with the target (i.e., callsign and frequency systems, address tables, etc.) are largely solved or understood; and

[] where we have good prospects of being able to project the appearance and behavior of the target from day to day.

(U) In development TA (the training communications in our example), we have a pattern-searching problem,

[] where the emphasis is on sifting through masses of low-yield ore, looking for something that forms a continuity;

[] where the next success may look nothing like the last one; and

[] where the chances of finding that needle in the haystack may depend as much on the personality of the searcher as on the content of the haystack.

If we can't keep continuities, (i.e., are not able to), then the target stays in the development phase, no matter how much we know about it. Someone once said that TA continuities take either 95% of our resources, or 5%. That number may not be right, but the idea is. Being able to keep track of the continuities is the key to whether the problem is development or maintenance in nature. A daily-changing callsign system looks to us as if it is rapidly changing if we haven't solved the system, but once the system is solved, we then perceive it to be slowly changing. It is a matter of viewpoint.

(U) In maintenance TA, we work largely with what the target gives us. A package of techniques to grapple with a callsign system may work well enough on a problem where the callsigns are the key to our keeping track of continuity, but may be almost useless on another problem where the callsign system isn't solved and we must rely on other things, such as serial numbers or addresses.

(U) In development TA, on the other hand, a particular technique may pull one new structure out of the search pile and then never again find anything. The development analyst may need to continually devise new attacks and new methods; to him, the search pile is a featureless mass and it is his job to sort out the various pieces and find ways to distinguish one piece from another with some reliability.

(U) The maintenance TA problem probably needs a package that will

[] look over the incoming material for the day;

[] make reasonable guesses about continuities (including garbles);

[] flash a warning light at the traffic analyst when things look very wrong or when it is confused by something; and

[] provide a clean and readable summary of its results to the analyst for review.

It ought to keep up with both short-term and long-term trends, and should be especially attentive about "missing persons," portions of the target which haven't been seen for a while.

(U) The development TA problem, on the other hand, needs a toolkit that will provide the analyst with a range of diagnostic, computational, and pattern-searching techniques that can be brought to bear on the problem, in whatever mix the analyst needs at the moment.

WORST CASE

(U) I have shown what might be called the "worst case" for each of these forms of traffic analysis.

(U) In maintenance TA, one sometimes finds that a problem must somehow be worked, but that it has no real resources and not enough clout to get any. Now, in the best of all worlds, where everything is done right and for the right reasons, such problems should not exist. If a problem is worth working on at
all, it is worth the resources needed to get the job done. However, in the real world, those problems that are "below the salt" will always be working with whatever support they can be, borrow, or scrounge. Providing a general package for such problems would pay for itself a hundredfold in the first few years. At the minimum, package needs to be able to "ring an alarm bell" when the target starts to disappear, or becomes more active, or changes in some other way.

(T) (C) In development TA, the worst case might be the situation where nothing is known. That is not as uncommon as some people might think.

When we pull together an analysis effort for a sudden war or brushfire, the analysts are usually drawn from other problems around the building; it would be nice if they didn't have to add "learning a new system" to all the other problems they will face on the new target. Therefore, the toolkit for such situations must be quite general and all-purpose.

TWO SYSTEMS OR ONE?

(U) What I have been describing so far may sound like two different systems, but what I am proposing is one system, with two parts. I have already said that these two phases or aspects of TA occur together, and I should add that on more than one problem, they are frequently done by the same people. New continuities are recovered by the development TA process, and then handed over to the maintenance TA effort to be kept track of. Information is often derived by the maintenance effort that will help the development effort. What the traffic analyst needs is one system that has enough flexibility for him to move whichever way his TA problem takes him. It would also be useful if the language we use is one that isn't going to change every few years because some equipment in the basement is being upgraded.

PINSETTER

(U) Several years ago, we began to work on the concept of a Traffic Analysis Workbench System, with the covername PINSETTER. Some of what I have described here comes out of that experience. PINSETTER has been described elsewhere, so I will not spend time on it here. However, I will share with you some of my personal conclusions about PINSETTER, especially those which seem to be pertinent to the future.

(U) There are aspects of traffic analysis which resemble word processing, and a good screen editor seems to go a long way toward putting the analyst in contact with his traffic, letting him rearrange it and touch up the rough edges and garbles the way he (the owner) wants them. It lets him look at the data before he decides what processing to apply to it. It also puts him in a good position to generate reports about his problem, especially the technical reports with technical data embedded in narrative text.

(U) A good toolkit, similar to UNIX and the PINSETTER extensions, is invaluable in providing the traffic analyst with the ability to tailor-make his own flexible processes for large scale manipulation of his traffic.

PROBLEMS THAT NEED SOLVING

(U) Among the many problems that need to be solved, I would like to mention two. Both of these are areas that are critical to the future TA Workbench System.

ARCHIVES

(U) Some of our continuities form chains that stretch back to the end of World War II. One of the things that Data Systems people don't like to hear is that we need storage for data whose lifetime must be measured in years, and perhaps decades. Some years ago, there came a time when all of our incoming data went solely into the computers in the basement. It was the culmination of the dreams of a number of people: to take the raw traffic away from the analyst! I don't challenge that decision. It is history. But I must say that on many TA problems around the agency, there are no good records on our known continuities from that date forward, unless there were analysts still keeping some sort of hand records. The philosophy on most computer hosts is that any records not accessed within some period (usually a year or less) are taken off the system.

(U) Even if the data is put onto tape, the medium will deteriorate. Once on tape, the data is "out of sight and out of mind." The software that understands that data will sooner or later disappear or be "improved." Nevertheless, the analysts on that problem are still responsible for that period of time, and may still have to field questions about their
targets for that time period. So far, we have dodged this bullet, but sooner or later we will have to face the need for long term archives.

INFREQUENT USE OF PROCESSES

(U) The second problem involves the question of software that is only infrequently used. For example, suppose that one of our larger targets has a major communications change every five or six years. The effect of this change is so great that it interrupts intelligence reporting on that target until the new communications structures are understood and recovered. Each time the change occurs, an intensive effort is therefore mounted to recover our continuities in the shortest possible time.

(U) In the old days, when the special effort was over, everything was bundled up and packed away for retrieval when the next change came along. But how do we handle this now that we have modern data systems support? After five or six years, how much of the software is still useful? Chances are that the data base has been changed, as well as the host on which it resides.

(U) Another example might be the diagnostic techniques to attack a particular kind of callsign system. Once the system in question is solved, how should we preserve the software so that it doesn't need to be reinvented the next time such a system is encountered? Suppose we don't find a similar system for five, or six, or even ten years?

CONCLUSION

(U) I don't offer either my observations or my experiences as criticisms, but rather as areas of traffic analysis support which need to be solved. I have tried to avoid mentioning specific hardware or software, except as examples. A man named Bob Biles taught me long ago that users should never tell computer people what equipment to use.

(U) Perhaps traffic analysis has lagged behind other cryptologic disciplines in making full use of modern data systems. But that is changing, thanks to the patience, ingenuity, and hard work of many of you here today. I still keep a supply of pencils around, and I still have a pencil sharpener on my desk—but I have noticed that I don't really use them very much any more.
N.S. Norway (1889–1960) was an aeronautical engineer, active during the pioneer days of British aviation. He was also a prolific novelist. Many of his best works are set in the country which became his post-WWII home. Mr. Norway is Word V in this puzzle.
